Power System Resilience (Draft)

Georgian State Electrosystem

Georgian Transmission Network 2010

- Georgian Transmission Network was designed for parallel operation with the North Caucasus and Armenia/Azerbaijan power systems. Hence 500 kV grid which had radial topology in territory of Georgia, was backed up by three neighbor countries simultaneously;
- Generation of the HPPs located in the West Georgia was transmitted to Russia, while the power plants located in the East Georgia were supplied with fuel from Azerbaijan;
- Starting from 90's, due to the independent reasons, there was no possibility of parallel synchronous operation with more than one neighboring country, which caused leaving internal radial network of Georgia as well as any operating interconnection line without backup.

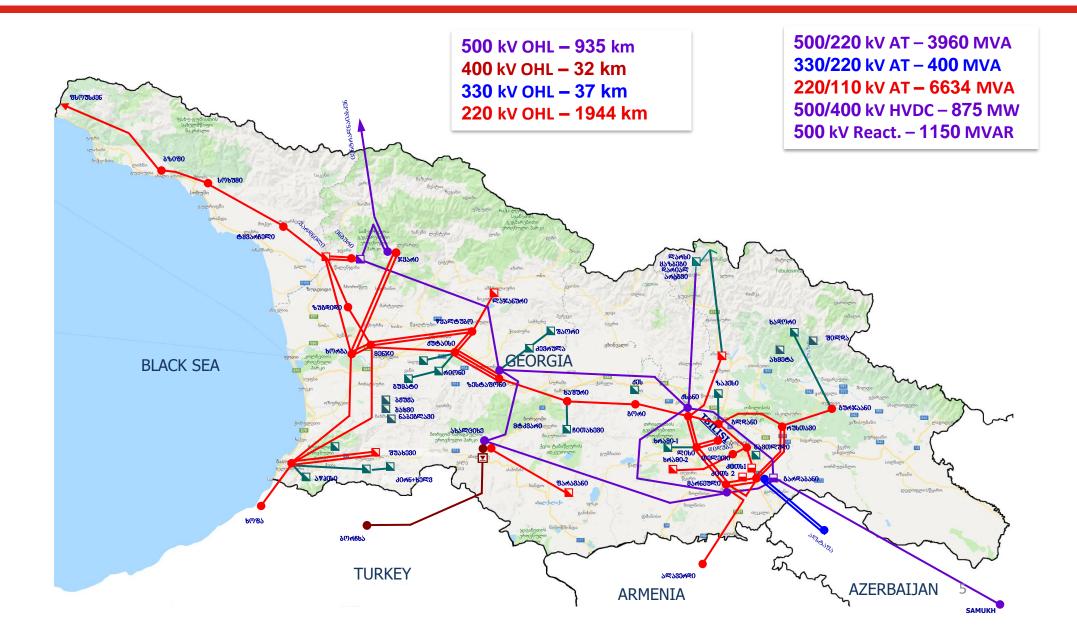

Challenges of Georgian power system stability

- Nowadays, parallel operating with only one neighbor country (either Russia, or Azerbaijan) and interconnection problems:
 - N-1 criteria with Russia;
 - Limited power flow with Azerbaijan.
- Lack of speed governors and low inertia phenomenon due to the small size of Georgian power system (minimum load equals to 1,000 MW), outage of biggest generators (250 MW installed capacity) without RAS intervention can cause stability problems;
- Main generation objects located in the western part of Georgia and consumption in the eastern. Their interconnector 500 kV backbone isn't fully reserved and N-1 criteria isn't fulfilled.

Existing Transmission Grid of Georgia

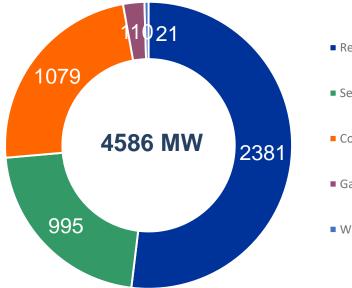

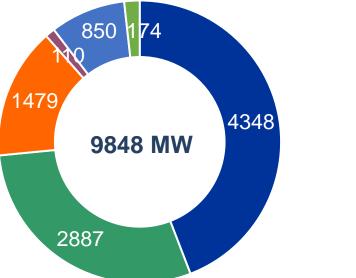

Existing and Planned Installed Capacity of Generation

Sources

- Regulating HPPs
- Seasonal HPPs
- Combined cycle and coal TPPs
- Gas-Fired Turbines
- Wind Farms

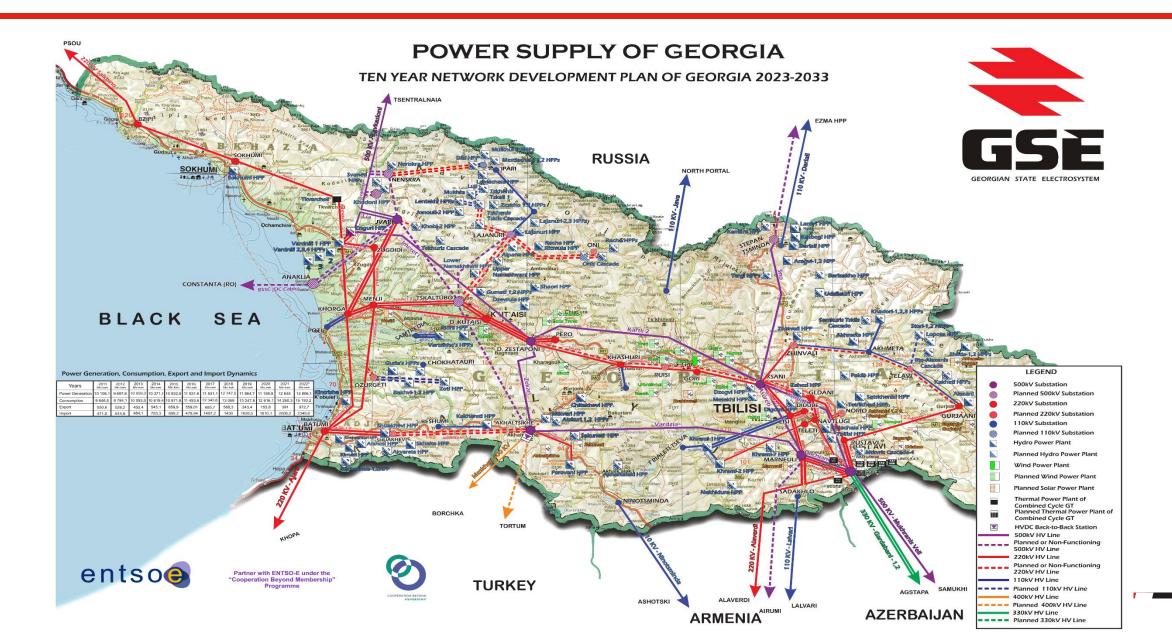

Installed capacities of the existing power plants

Installed capacities of power plants as for 2033

Georgian Transmission Network 2023-2033

Power system resilience is the ability to limit the extent, severity, and duration of system degradation following an extreme event

A summary of the main risks to be addressed are:

- Extreme natural events, such as earthquakes, hurricanes, floods, wildfires, tsunamis
- **Cyber and physical security vulnerability, including Electromagnetic Pulse (EMP)**
- □ Inadequate system state awareness
- **Changing resource mix**
- **D** Bulk power system planning, adequacy and performance
- □ Lack of skilled workforce

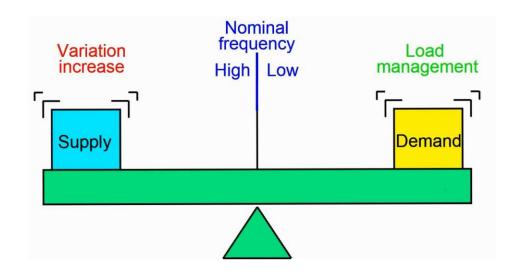

Power system resilience is achieved through a set of key actionable measures to be taken before, during, and after extreme events, such as:

- Anticipation;
- Preparation;
- Absorption;
- Sustainment of critical system operations;
- Rapid recovery;
- Adaptation;
- Application of lessons learnt.

In power system operations, resilience generally means the ability to respond quickly to and recover from a disruption.

- In Emergency Situations Action Plan Provides:
- \circ $\,$ Automatic and manual load shedding $\,$
- Triggering of Remedial Action Schemes (RAS) complex
- Manage constraints in synchronous state
- \circ Restoration of supply

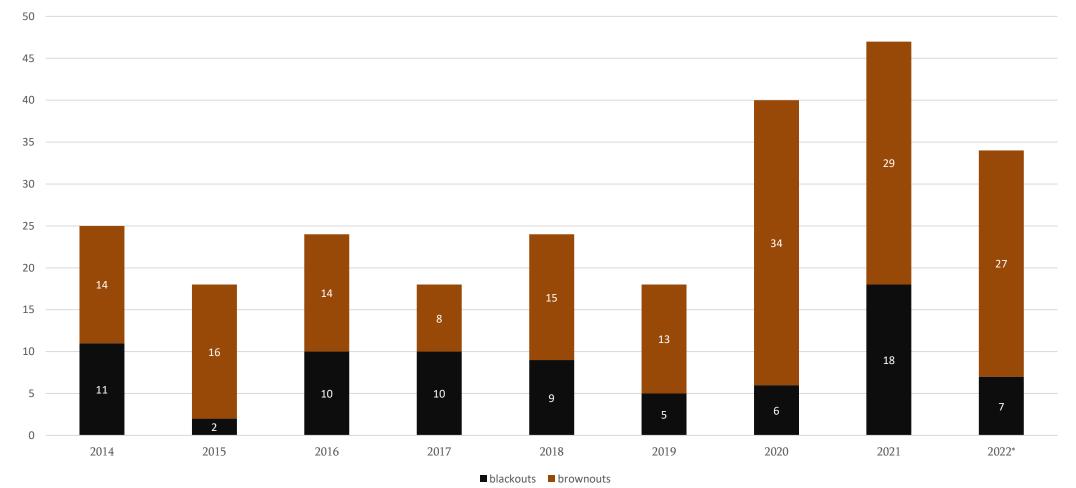

- The RAS devices maintain static, dynamic and resultant stability of the power system. They respond in both cases, when the network is operating in steady mode, or when one of the transmission lines is under maintenance outage;
- RAS devices continuously monitor the status and operating regimes of the system elements, identify and record hazardous events or abrupt violation of the normal regimes, assess their severity and, in case of emergencies, send signals to the logic processor that compares sequence and intensity of the signal and selects the relevant response command (generation reduction, load shedding or both);
- Under the single contingency (N-1), in case of active power excess in the system, RAS will initiate rapid automatic reduction of the active power generation in Enguri HPP, while in case of active power shortage, will shed the load (in the country) and, if needed, the export (re-export).

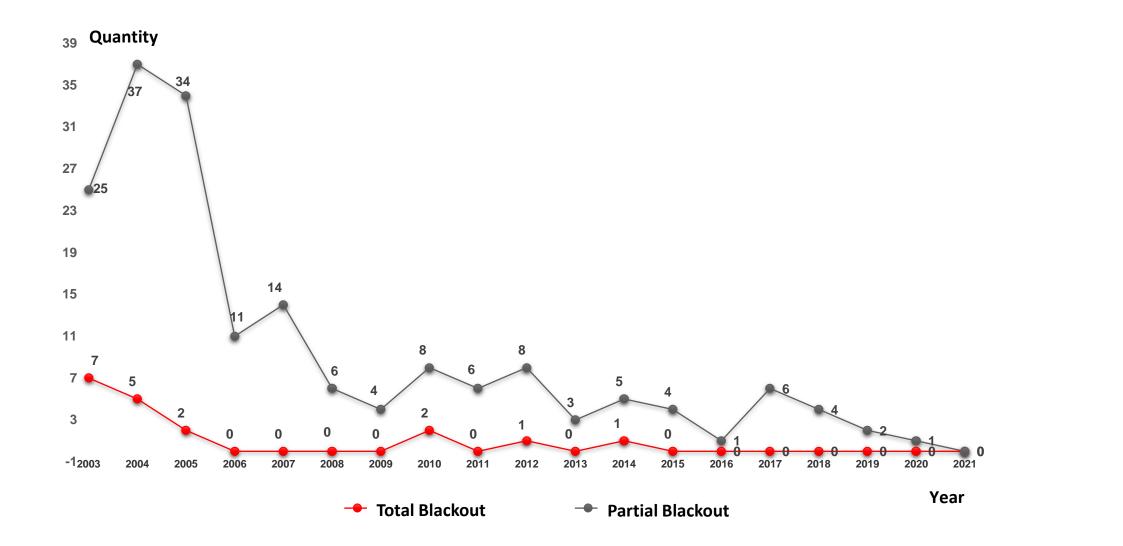

Annual statistics of saving from Blackouts & Brownouts by RAS

Blackout Statistics 2003-2021

13

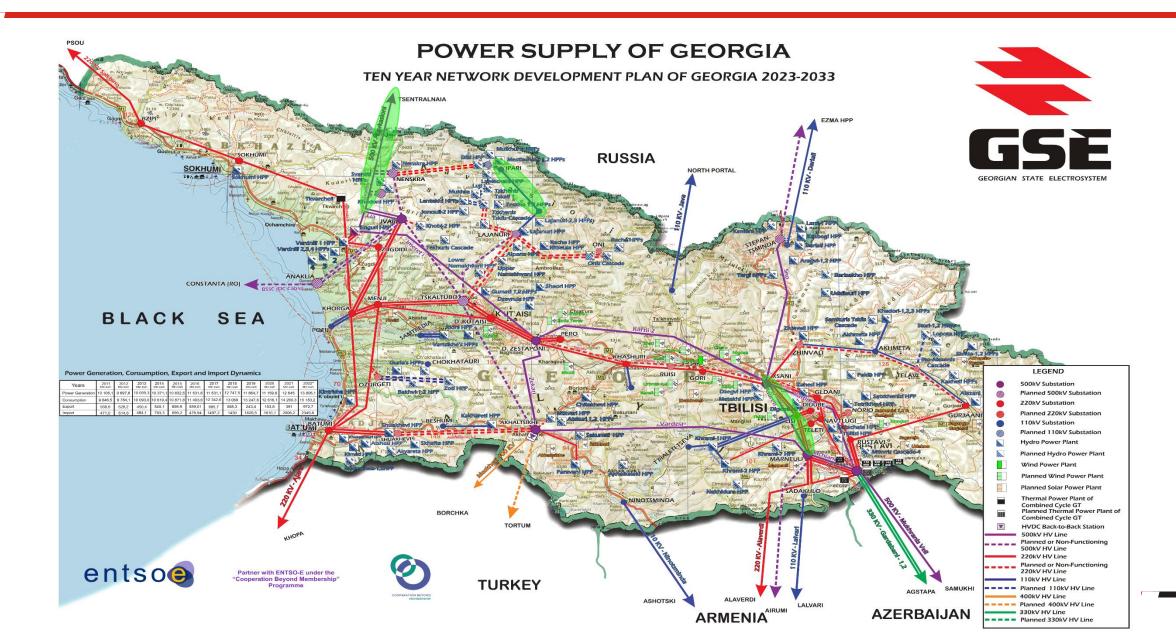

• Black-start program has been elaborated in GSE in 2015. This program included list of the existing power plants capable of black-start service.

• Emergency trainings for operational staff of Dispatchers of National Control Center (NCC) are performed in simulation exercises to check the level of training of dispatchers and to study the methods of restoration of the power system in case of emergency situations. Emergency trainings are carries out on a quarter basis.

Georgian Transmission Network 2023-2033

Damaged Infrastructure of 500 kV OHL Kavkasioni

Damaged towers 110 kV OHL Ifari

Ice Cover on 220 kV OHL Didgori – 1,2

Damaged Towers and Insulators of 220 kV OHL Koda 1,2 caused by heavy Hail and Hurricane

Out of ordering of cooling system of server caused increase of temperature in server rooms above their critical range. As a result, access of IT and SCADA users to control and monitoring software Spectrum has been totally terminated. Mentioned incident put GSE's critical importance main and backup infrastructure under the risk, which itself could cause negative results which much higher scale in whole electro system.

According to the conclusion of data center audit, emergency outage of "precision conditioner" installed in the server rooms in substation "Navtlughi-220" has been result of "High Pressure" flaw. Second conditioner was not able to sufficiently cool server rooms, due to which room temperature has been increased up to 45°C critical level. Based on above-mentioned, process development was the reason of starting emergency mode of the servers and total shutdown of their part after specific period. Reserve dispatch center of SCADA system remained in operation. However, access to Spectrum software for SCADA system users has been terminated during elimination of mentioned technological disruption (30-40 minutes).

- Procurement of technical support for UPS and cooling system located in server facilities has been implemented. Fault caused by incident has been eliminated in framework of the contract and monitoring and technical service of UPS and cooling system is done on a regular basis
- Respective instruction has been elaborated by SCADA and IT department administrators in order to implement necessary measures with respective consequence in case of similar incidents in order for their elimination
- In order to ensure uninterrupted operation of IT services, including telephone system, the project of procurement of high-performance servers and network equipment compatible to the modern technologies and of introduction of scheme of uninterrupted operation (active – active) of data centers in ongoing
- For the purpose of arrangement of alarm system for server infrastructure temperature monitoring and critical temperature, arrangement of reserve independent SMS system is planned

Identification and Evaluation of the Electricity Crisis Scenarios

- On December 2, 2020 was approved the Security of Electricity Supply rules;
- Regarding the Annex 1 of the SoS rules TSO has to identify relevant electricity crisis scenarios for Georgia in close cooperation with the Ministry of Economy and Sustainable Development of Georgia;
- According to the SoS rule GSE is also preparing Risk-Preparedness plan, that is under development.

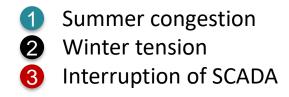

Evaluation of scenarios Steps

- 1. Determine likelihood of scenario
 - Identify class of likelihood

Classification	Events per year	1 x in years	Description/example of initiating event
Very likely	≥ 0.5	2 or less	event expected practically every year, e.g extreme winds/storms causing multiple failures of overhead lines may be expected nearly every year in some areas
Likely	0.2-0.5	2-5	event expected once in a couple of years e.g. extreme heat wave causing limits or output of open-loop water-cooled power plants, low water levels at hydro plants higher load, etc.
Possible 2	0.1-0.2	5-10	event expected or taken into consideration as a potential threat, e.g. cyber or malicious attack
Unlikely 3	0.01-0.1	10-100	very rare event with potentially huge impact e.g. simultaneous floods causing unavailability of generation, distribution and transmission infrastructure
Very unlikely	≤ 0.01	100 or more	event not observed but potentially disastrous, e.g. earthquake causing a huge destruction of transmission, distribution and generation infrastructure

- 2. Determine impact of scenario
 - Identify class of impact :
 - By use of risk indicators: EENS, LOLE

Crisis Impact Scale					
Classification	EENS%	LOLE			
	(of annual demand)	[hours]			
Disastrous	≥0,25%	≥168			
Critical 23	≥0,05% and <0,25%	≥48 and <168 2			
Major	≥0,01% and <0,05%	≥12 and <48 1			
Minor 1	≥0,002% and <0,01%	≥3 and <12			
Insignificant	<0,002%	<3			

Electricity Crisis Scenarios

Summer congestion

Interruption of SCADA

Winter tension

Evaluation of scenarios Steps

Scenario	Likelihood	EENS%	LOLE
1	Likely	Minor	Major
2	Possible	Critical	Critical
3	Unlikely	Critical	Critical

Support for the numbers:

- Likely: 1 every 2-5yrs → 20-50% probability
- Possible: ... 5-10yrs \rightarrow 10-20% probability
- Unlikely: ...10-100yrs \rightarrow 1-20% probability
